# OVERVIEW

## CLIENT

Tourism New Zealand are an organisation which promotes New Zealand internationally to gain more tourism and growth to the economy. With an arrival of 3.7 million visitors each year, Tourism New Zealand take upon the responsibility to ensure New Zealand is remained attractive to travellers of kind.

## REQUIREMENTS

- Create a single page web application in which users can input their options
- Be responsive for tablet and desktop

- Validate the information provided and give meaningful feedback if the validation is correct or incorrect
- User should be able to see the results of all their options selected
- No errors occur in the console

## TRAVEL COMPANION

In order to continue this success with a one page app.

This is where Travel Companion will solve all tourists problems for booking accommodation within Auckland. By filling in their details on the app, users will be presented with

a range of accommodation options via an interactive map for them to view and book. In addition to this, users will get a summary of their options and accommodation along with the total cost of everything.

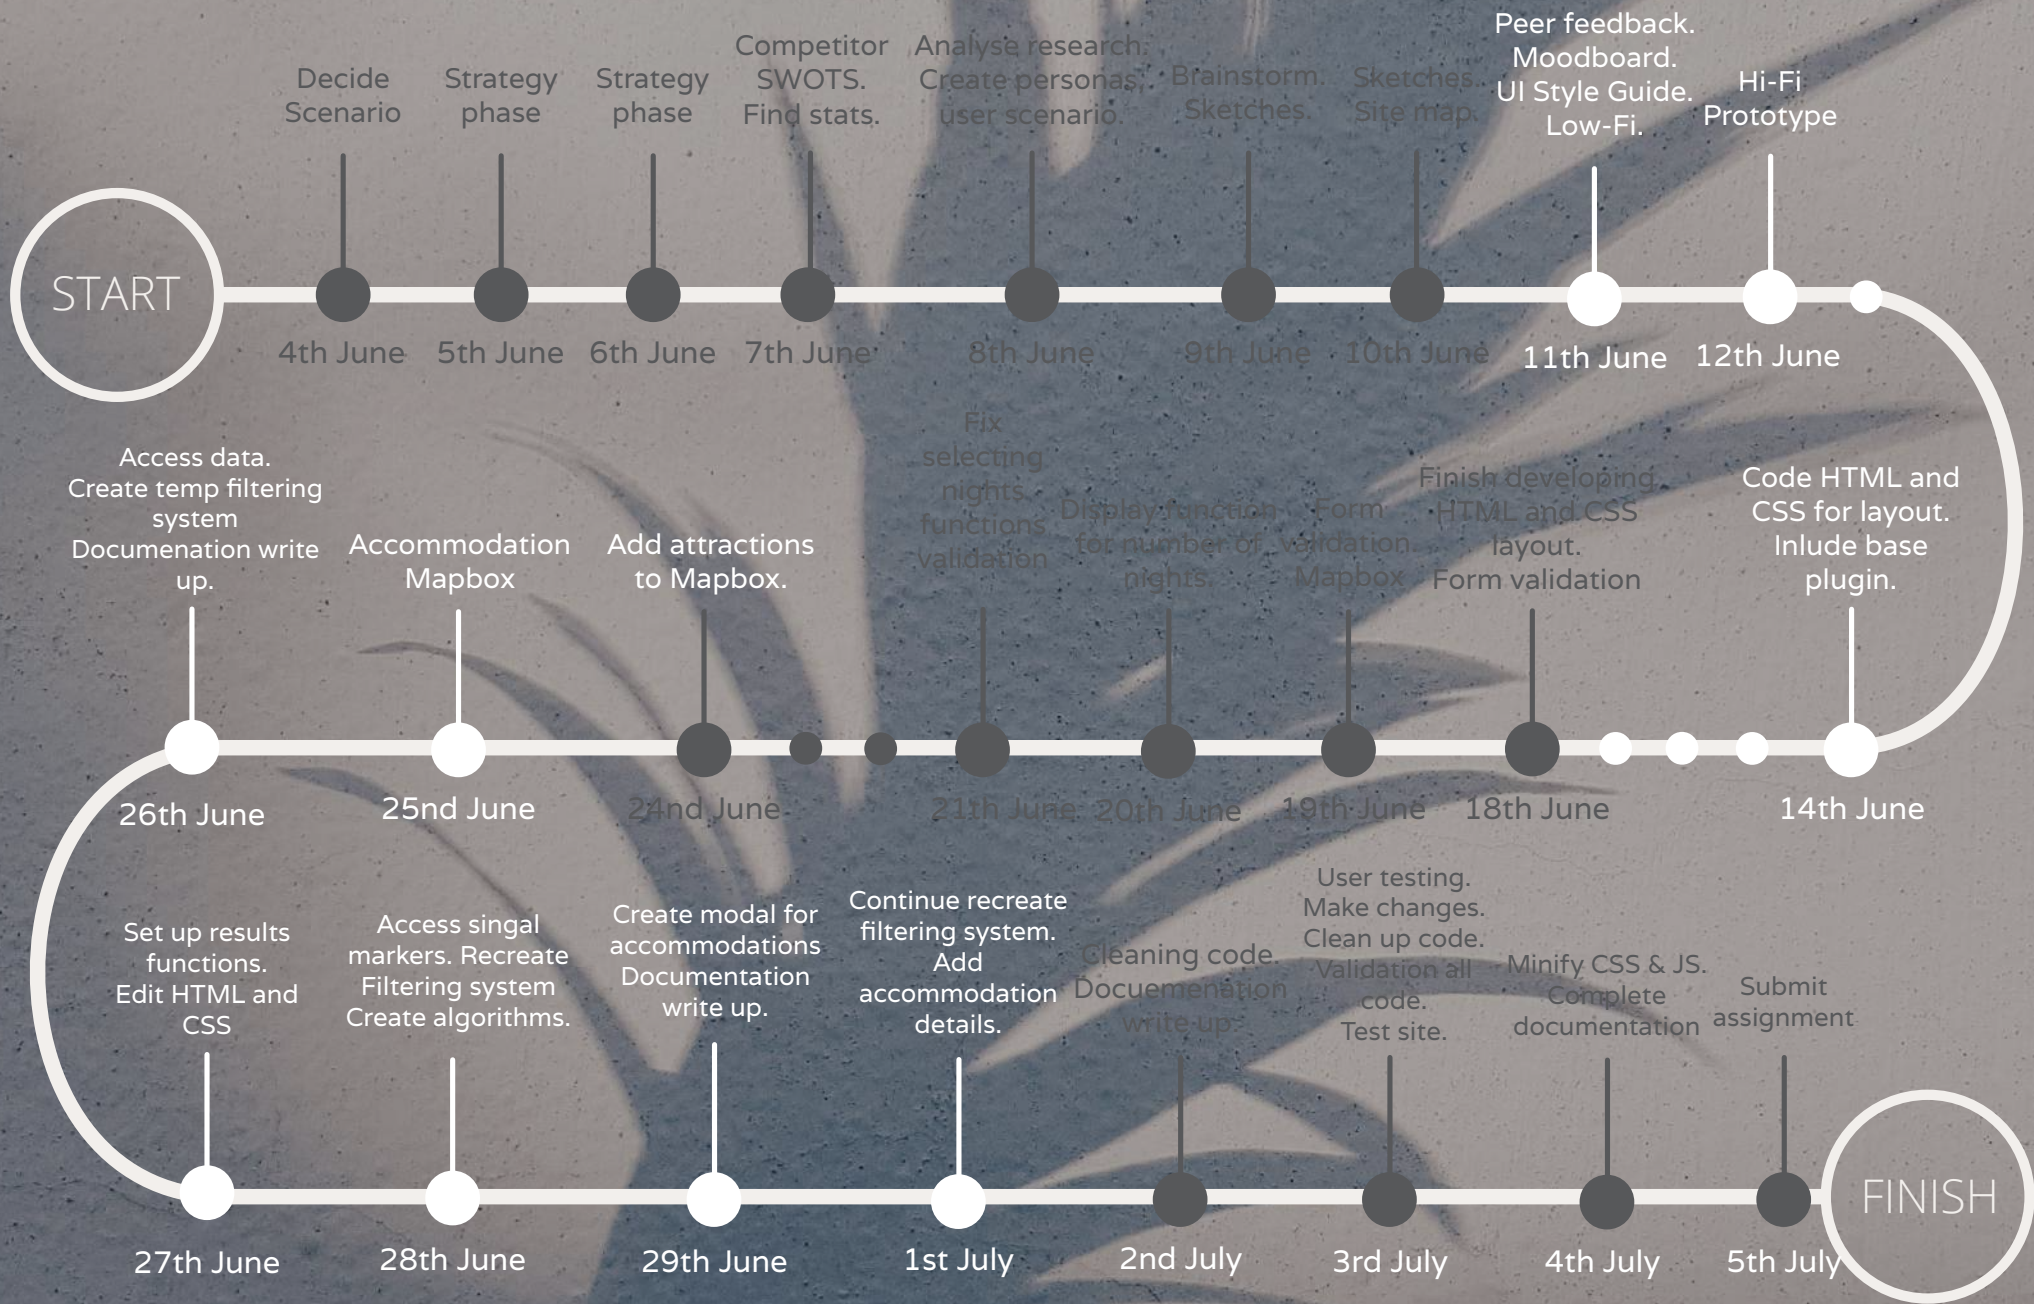

## LINKS

TRELLO BOARD (planning): <https://trello.com/b/W2z61o2V>

GITHUB REPO: <https://github.com/sumitramanga/Travel-Companion>

LIVE SITE: <https://sumitramanga.github.io/Travel-Companion/index.html>

# TIMELINE

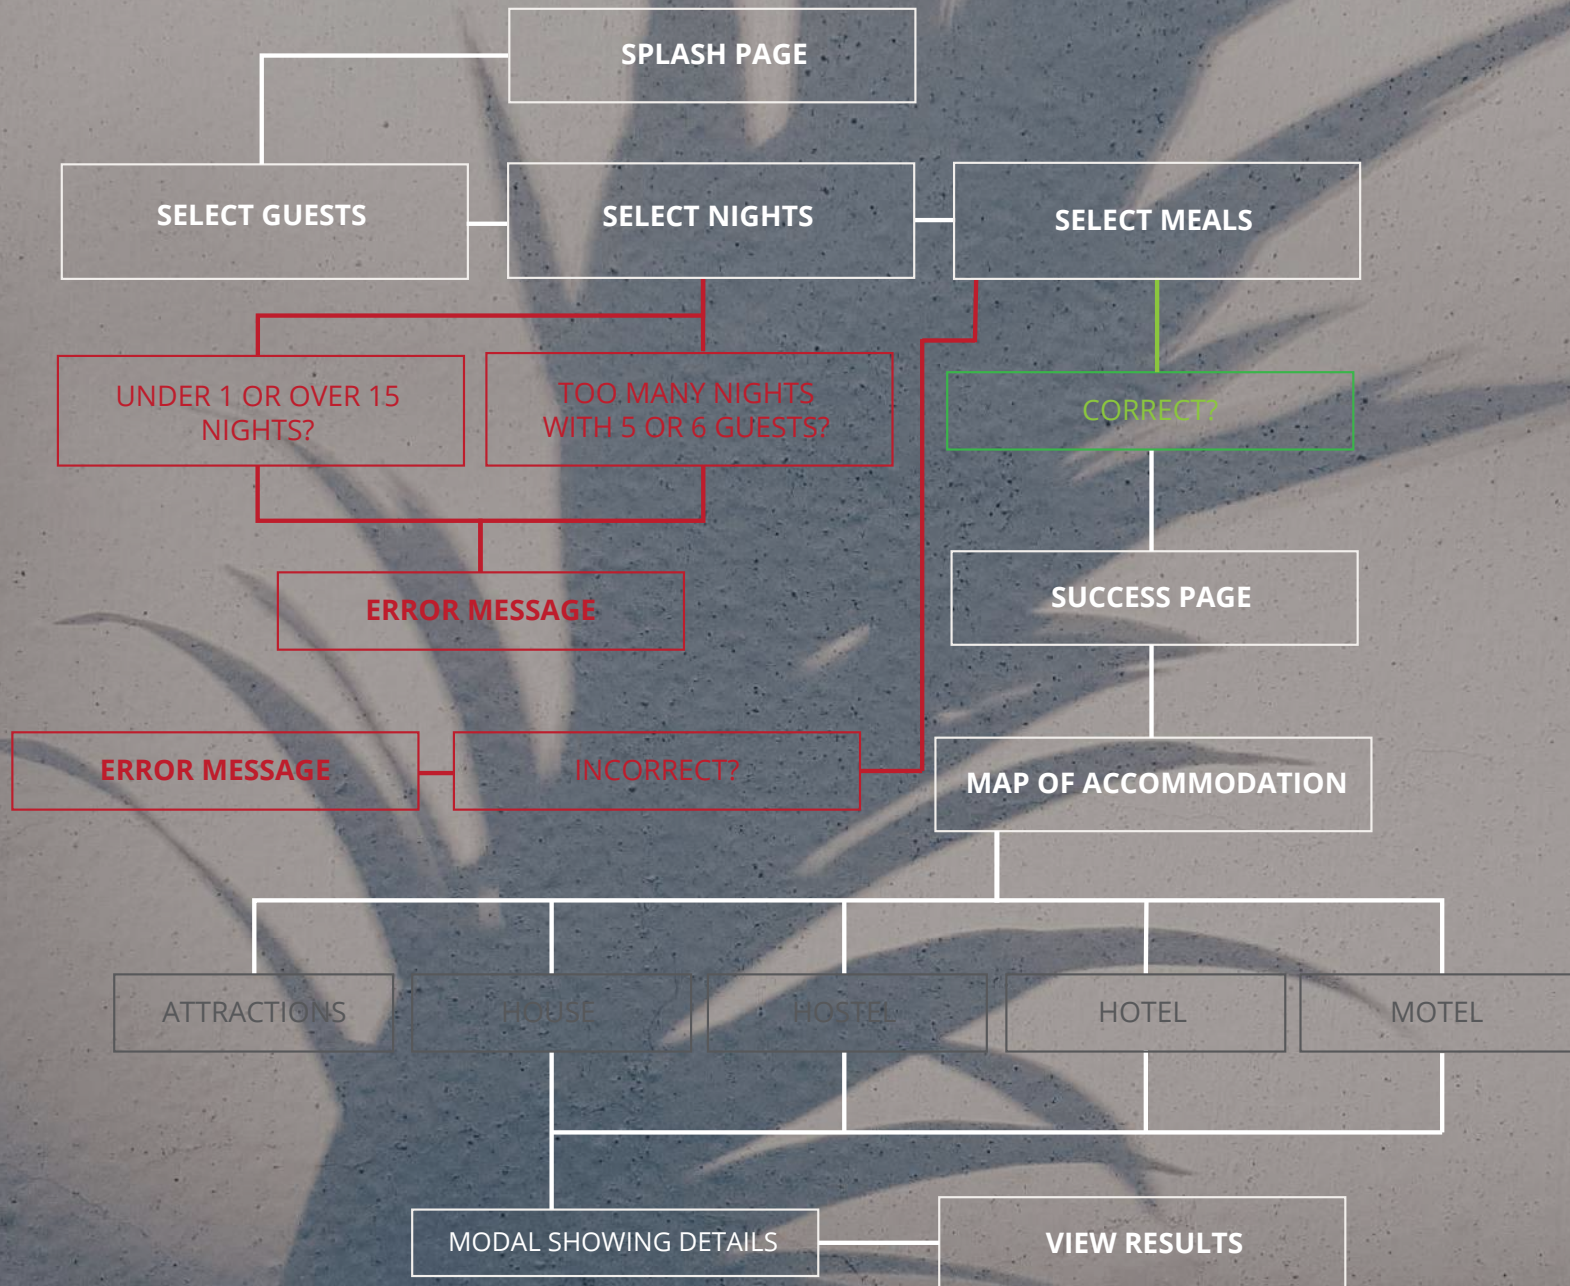

# DELIVERABLES

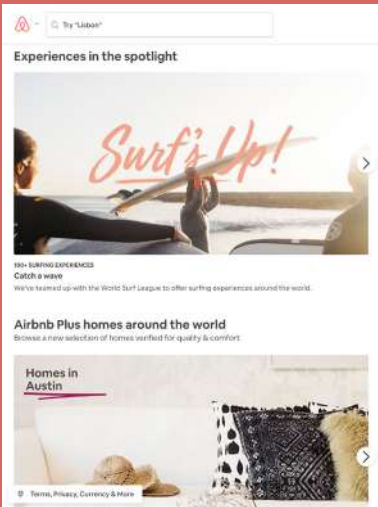

- Create the template of the app (the base) which has a consistent theme throughout all sections
- Have a form that validates whether the information is correct or incorrect and show the user this
- Display attractions near by the accommodation on the map to give the user ease of where and who to book their accommodation with
- Show where accommodation is available based on the information the user has submitted via an interactive map
- Output the results to show the user what they have selected and to help confirm that the details are correct

# BUSINESS STRATEGY

The business strategy that needs to be approached is to continue the tourism market within New Zealand. Making sure that people continue to travel for holiday purposes or even business purposes needs to be shed light on as it makes up for the largest earner of foreign exchange. Making sure consumers have a easy painless journey from the start of making the travel plans to the end of their journey in New Zealand is something we'll focus on with this app. Also making sure that commuters/local travellers will be needed to focus on as they also help shape the economy today. If this were to be successful, we will then look further into adding more features such as completing the booking on the app.

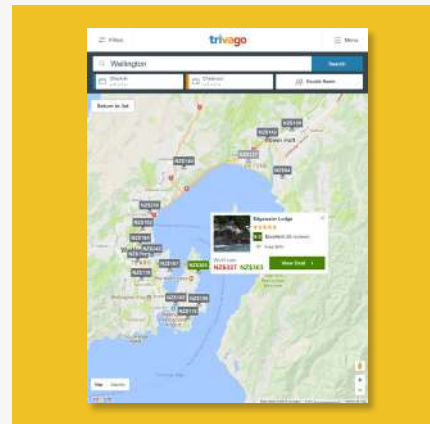

# USE CASE DIAGRAM

# Travel Companion

Travel Companion is an app to find accommodation within Auckland. Travel Companion is an app to find accommodation within Auckland. Travel Companion is an app to find accommodation within Auckland.

# MOOD BOARD

A clean simple mood board was created to reflect the app's friendliness whilst staying modern and professional. Inspiration for the app was taking from existing accommodation related websites such as Airbnb and Trivago. The clean pure look gives off a luxurious feel which is to entangle our audience who are self-indulgent.

## CODE STYLE GUIDE

- Single quotation marks
- camelCasing when assigning names to variable and other elements
- Indentation is created using tab key
- All variable names start with a letter
- Scripts are external
- Code is well commented to explain the functions
- Gulp has been used as a linting tool
- Logically named functions

# FEEDBACK, USER TESTING AND VALIDATING CODE

## FEEDBACK

I have received feedback from my initial sketches for the app. I had chosen the sketches which were more preferred and I was suggested to have a success page which showed that after the details are filled out the user can feel a sense of relief that they can now browse for accommodation.

## USER TESTING

ASSIGNED TASKS:

- Navigate through the entire app
- Be able to view their results

The user testing participant likes the colours fonts, buttons are visible, and how easy it is to navigate. The participant felt that the colour of the error messages clashed with the with the background colour. They

suggested to have a pop-up or to change the colour though they felt the colour was appropriate for its use. I changed the colour to a much brighter red that stand out. Another problem the participant had was getting confused when filling in the details as the arrow buttons stayed. Due to the amount of the time I was unable to fix this even though it was apart of my prototype. They also like the shadows on the map and the box as they feel it is less flat. Another thing I had noticed was that the laptop screen size did not fit the content of the screen. I had created a media query to fix this issue.

## VALIDATING CODE

I have validated HTML and CSS using the W3C validation site. Both are clear of errors although the HTML displays warnings. One of which is the script type being

unnecessary. This is due to the fact that the validator is validating to the HTML5 standards. I have kept the script type in case it is needed as we were taught in class to use this attribute. The other warning is that a h3 tag is empty. This element is empty as it is reserved for Javascript manipulation. After the user has selected an accommodation type, the Javascript manipulates the element to display the name of the chosen accommodation.

The Javascript was validating through Gulp using the linter whilst coding the app.

# JAVASCRIPT LIBRARIES

## MAPBOX

<https://www.mapbox.com/>

The API Mapbox is used to show accommodations via a map with markers locating where each accommodation is located along with their details.

## JQUERY

<https://jquery.com/>

jQuery was used to add functionality to the interface as well as click event. jQuery was also used in conjunction with other plugins such as pagePiling.

## BOOTSTRAP

<https://getbootstrap.com/>

Bootstrap version 4.0 was used to create modals for the help section and view an accommodation choice. Bootstraps form validation was applied to the inputs on the app which shows useful messages when the information provided was incorrect. The grid system was also used within one area of the app which is to inline the logo and “Start over” button.

## FLAT ICON

<https://www.flaticon.com>

Flat Icon was used to for the UI pins on the Mapbox markers.

## FONT AWESOME

<https://fontawesome.com/>

Font Awesome is used throughout the app to replace words with icons within the splash page and results page to create a positive and friendly approach for the UI of the app.

## MAKI ICONS

<https://www.mapbox.com/maki-icons/>

Maki Icons are a library installed within Mapbox. These icons were used to mark down attractions within Auckland.

# PLUGINS

## **NODE.JS**

<https://nodejs.org/en/>

I have used node.js to test out Javascript within terminal on data which I have created. This was tested through console.log and creating if statements to access properties of objects.

## **GULP**

<https://gulpjs.com/>

I have used gulp to reduce key strokes when refreshing the page. This means that gulp is “watching” the certain files to invoke a live loader. Gulp was also used as a linter for the custom Javascript file, compiler for the SASS, and minify the custom CSS.

## **PICKADATE.JS**

<http://amsul.ca/pickadate.js/date/>

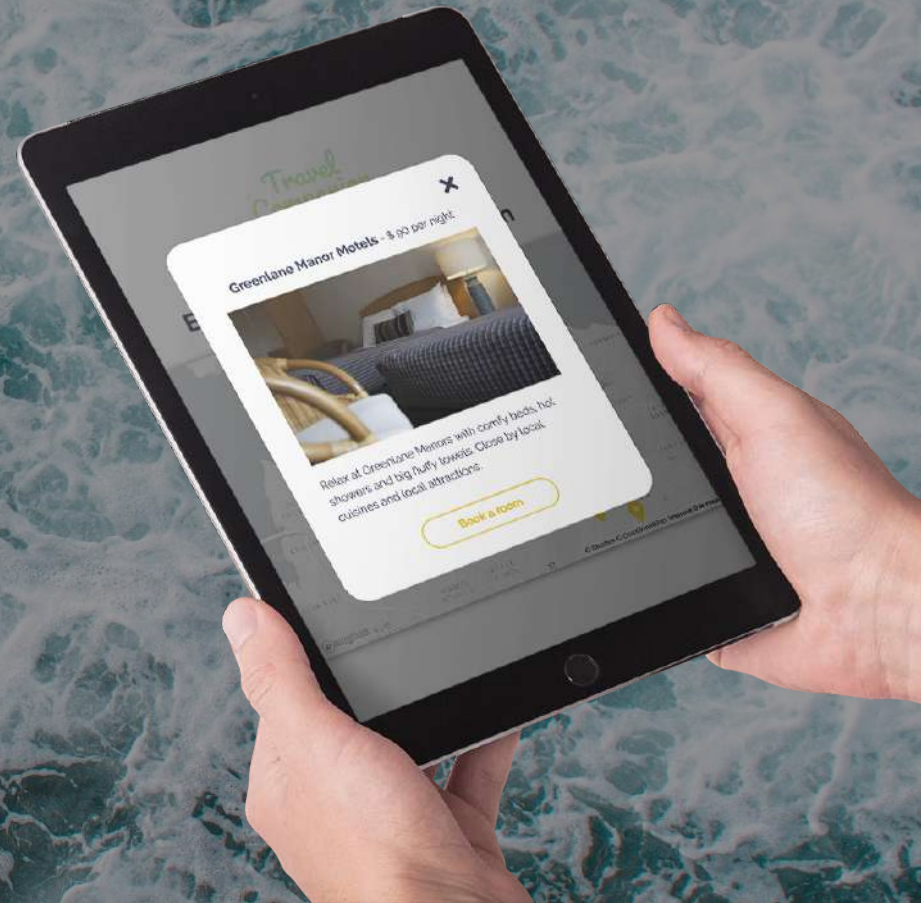

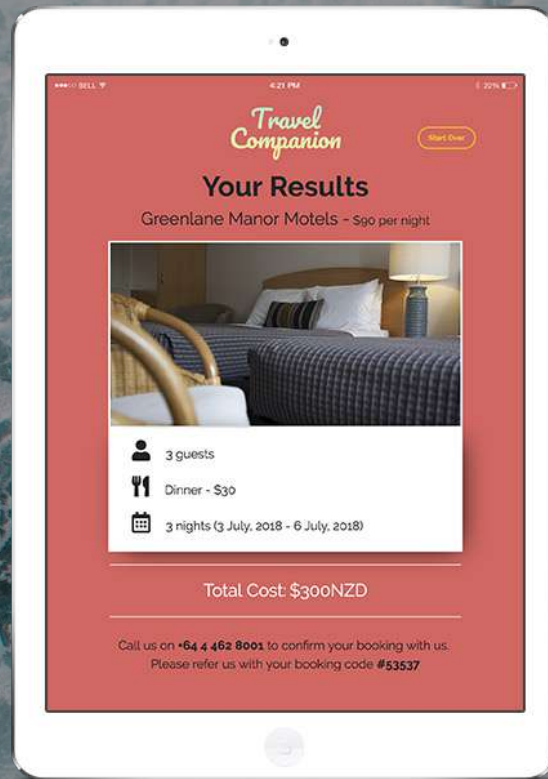

pickadate.js was used for the UI component for the app. This is so users can engage with the app by interacting with it instead of having to type in the date.

## **PAGEPILLING.JS**

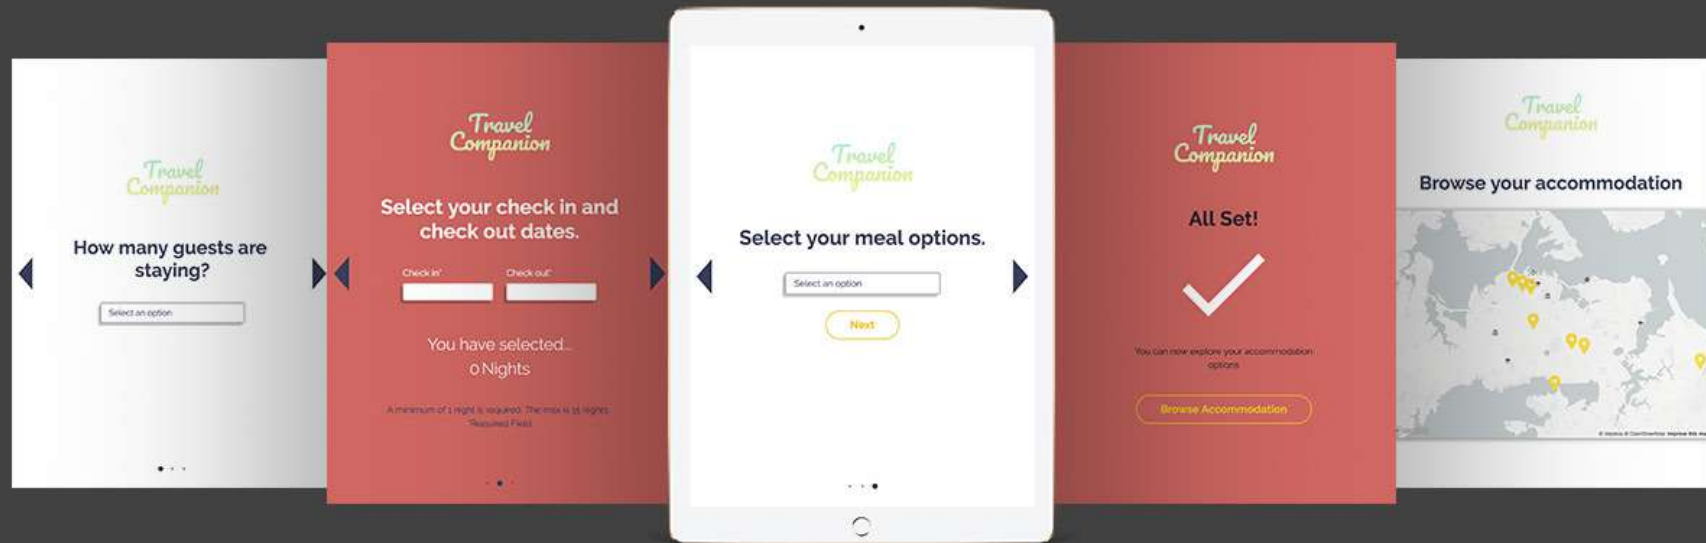

<https://alvarotrigo.com/pagePiling/>

pagePiling.js was used for the UI side of the app as well. This plugin adds a modern touch to a flat app. Flowing smoothly through each section and slide of the app, this plugin keeps users interested throughout using this Travel Companion.
